Efficient computation of the Hasse-Weil zeta function

Wouter Castryck Efficient zeta function computation

코 > - 코

Problem I:

Develop an efficient algorithm that determines the number of zeroes of any given polynomial $f(x_1, \ldots, x_n)$ with coefficients in a finite field \mathbb{F}_q .

$$f \longrightarrow \# \{ (a_i) \in (\mathbb{F}_q)^n \mid f(a_1, \ldots, a_n) = 0 \}$$

Naively checking for every $(a_1, \ldots, a_n) \in (\mathbb{F}_q)^n$ whether $f(a_1, \ldots, a_n) = 0$ is not efficient!

 \rightsquigarrow takes at least q^n steps

◆□→ ◆ □ → ◆ □ → □ □

Write $N_k := \# \left\{ (a_i) \in (\mathbb{F}_{q^k})^n \, \middle| \, f(a_1, \dots, a_n) = 0 \right\}$ and define the zeta function

$$Z_f(T) = \exp\left(\sum_{k=1}^{\infty} N_k \frac{T^k}{k}\right) \in \mathbb{Q}[[T]]]$$

which turns out to be a rational function (Dwork) that can be algorithmically determined (Bombieri).

Problem II:

Develop an efficient algorithm that determines the zeta function of any given polynomial $f(x_1, \ldots, x_n)$ with coefficients in a finite field \mathbb{F}_q .

◆□→ ◆ □ → ◆ □ → □ □

In general, both problems are far from being solved (in every reasonable sense of the word efficient).

If $n = 1 \rightsquigarrow \text{solved}$

- polynomial factorization over \mathbb{F}_q (Berlekamp)
- count the number of linear factors
- If $n = 2 \rightsquigarrow$ good progress
 - reduce to irreducible case via

$$\#Z(fg) = \#Z(f) + \#Z(g) - \#(Z(f) \cap Z(g))$$

using polynomial factorization (Lenstra, Wan)

- irreducible-but-not-absolutely-irreducible case is easy (point enumeration) ~→ reduce to absolutely irreducible case
- use geometric and arithmetric properties of the curve Z(f)
- If $n > 2 \rightsquigarrow$ some generalizations, mostly only in theory

▲母 ▶ ▲ 臣 ▶ ▲ 臣 ▶ ● 臣 ● のへで

This talk: n=2, i.e.

- $f \in \mathbb{F}_q[x, y]$ is absolutely irreducible.
- Thus it defines a curve \widetilde{C} in $\mathbb{A}^2_{\mathbb{F}_q}$.
- Generalized zeta function: for any quasi-projective curve *C*/𝔽_{*q*} we define

$$Z_C(T) = \exp\left(\sum_{k=1}^\infty \#C(\mathbb{F}_{q^k})rac{T^k}{k}
ight).$$

Thus $Z_{\widetilde{C}}(T) = Z_f(T)$.

Note that $Z_C(T)$ only depends on the isomorphism class [C].

▲□ ▶ ▲ 臣 ▶ ▲ 臣 ▶ ● 日 ● の Q @

Theorem (Weil):

Let C be a smooth projective curve of genus g. Then we can write

$$Z_{\rm C}(T) = rac{P(T)}{(1-T)(1-qT)}$$

for a degree 2*g* polynomial $P(T) \in \mathbb{Z}[T]$. Moreover

P(T) factors as

$$\prod_{i=1}^{2g} (1 - \alpha_i T)$$

for algebraic integers $\alpha_i \in \mathbb{C}$.

For i = 1, ..., 2g we have $|\alpha_i| = \sqrt{q}$ (Riemann hypothesis).

For a suitable choice of indices, we have $\alpha_i \alpha_{2g-i} = q$ for i = 1, ..., g.

$$\blacksquare \# C(\mathbb{F}_{q^k}) = q^k + 1 - \sum_{i=1}^{2g} \alpha_i^k.$$

▲母 ▶ ▲ 臣 ▶ ▲ 臣 ▶ ● 臣 ● のへで

If C is any quasi-projective curve, and C is its complete nonsingular model, then

$$Z_{\widetilde{C}}(T) = Z_{C}(T)(1-T^{\kappa_{1}})(1-T^{\kappa_{2}})(1-T^{\kappa_{t}})$$

where $\kappa_1 + \cdots + \kappa_t$ is the number of 'points missing'.

The κ_i depend on the degrees of the field extensions over which these points are defined. In the case of a smooth projective g = 1 curve, we have the group law

For higher genus, a smooth projective curve C/\mathbb{F}_q can be embedded in a 'smallest' abelian variety $\operatorname{Jac}_{\mathbb{F}_q}(C)$ (it has dimension *g*).

Theorem (Tate): #Jac_{\mathbb{F}_q}(C) = P(1)

< 回 > < 回 > < 回 > -

臣

Most famous application and research motivation:

- Security is believed to depend on the hardness of the discrete log problem: given P and nP, find n ...
- ... which is easy if $\#E(\mathbb{F}_q)$ contains no big prime factors.

同トイヨトイヨト

First method. Computing in $\operatorname{Jac}_{\mathbb{F}_q}(C)$.

Idea:

- Arithmetic in $Jac_{\mathbb{F}_q}(C)$ can be performed efficiently (Hess, Khuri-Makdisi).
- Use this to compute the order of a generic point.
- Try to recover $Z_C(T)$ from $P(1) = # \operatorname{Jac}_{\mathbb{F}_q}(C) \dots$
- ... and some additional info if g > 1 (becomes hard when g gets big).
- Example: in genus 2, q odd, every ordinary curve C has a quadratic twist C^t. If

$$Z_{C}(T) = \frac{P(T)}{(1-T)(1-qT)}$$

then

$$Z_{C^{t}}(T) = \frac{P(-T)}{(1-T)(1-qT)}$$

 \rightarrow recover $Z_C(T)$ from P(1) and P(-1).

First method. Computing in $\text{Jac}_{\mathbb{F}_q}(C)$.

Shanks' method to compute $N = \# \operatorname{Jac}_{\mathbb{F}_q}(C)$ (case g = 1).

- By Weil's theorem: $q + 1 2\sqrt{q} \le N \le q + 1 + 2\sqrt{q}$.
- Choose a random point $P \in C(\mathbb{F}_q) = \operatorname{Jac}_{\mathbb{F}_q}(C)$.
- **Baby steps:** make a list of the first $s \approx \sqrt[4]{q}$ multiples

$$0,\pm P,\pm 2P,\pm 3P,\ldots,\pm sP.$$

Giant steps: compute Q = (2s + 1)P and R = (q + 1)Pand for $t = \lceil 2\sqrt{q}/(2s + 1) \rceil \approx \sqrt[4]{q}$, produce the list

$$R, R \pm Q, R \pm 2Q, \ldots, R \pm tQ.$$

Find match

$$R+iQ=jP.$$

- Then mP = (q + 1 + (2s + 1)i j)P = 0. If the match is unique, then $\#C(\mathbb{F}_q) = m$. If not, try another *P*.
- Running time is $O(\sqrt[4]{q})$. For $g \to \infty$, the advantage poured out of the Weil bound becomes smaller: $O(q^{(2g-1)/4})$.

State of the art: thanks to improvements by Mestre, Kedlaya, Sutherland, generic group methods make it feasible to compute $Z_C(T)$ for (roughly)

- q < 10⁴⁰ if g = 1, easily outperforms naive counting as soon as q > 10³
- $q < 10^{13}$ if g = 2

■
$$q < 10^8$$
 if $g = 3$

If one is only interested in $\# \operatorname{Jac}_{\mathbb{F}_q}(C)$, then also higher genera can be dealt with, over moderately sized finite fields...

伺下 イヨト イヨト

Second method. Computing in the Tate module.

Theorem (Tate):

For any prime ℓ different from the field characteristic *p*, and any $k \in \mathbb{N}$ we have that

$$\mathsf{Jac}_{\overline{\mathbb{F}}_q}(\mathsf{C})[\ell^k]\cong \left(rac{\mathbb{Z}}{\ell^k\mathbb{Z}}
ight)^{2g}.$$

Define

$$\mathcal{T}_{\ell}(\mathcal{C}) = \lim_{\stackrel{k}{\leftarrow}} \operatorname{Jac}_{\overline{\mathbb{F}}_q}(\mathcal{C})[\ell^k] \cong \mathbb{Z}_{\ell}^{2g}.$$

Let $\chi(T)$ be the characteristic polynomial of Frobenius acting on $T_{\ell}(C)$. Then

• $\chi(T) \in \mathbb{Z}[T]$ and does not depend on ℓ

$$Z_{\rm C}(T) = \frac{T^{2g}\chi(1/T)}{(1-T)(1-qT)}.$$

Idea (Schoof):

Compute

 $\chi(T) \mod \ell$

as the characteristic polynomial of Frobenius acting on $\# \operatorname{Jac}_{\mathbb{F}_{q}}[\ell]$ for various primes ℓ .

- Use the Chinese Remainder Theorem to recover χ(T) mod ∏ ℓ.
- If $\prod \ell$ is big enough, Weil's theorem allows us to recover $\chi(T)$.

◆□ → ◆ □ → ◆ □ → ● □ □

Second method. Computing in the Tate module.

In practice for elliptic curves $E: y^2 = x^3 + Ax + B$.

The characteristic polynomial of Frobenius is of the form

$$T^2 - tT + q$$

and we need to recover *t*. By Weil's bound, $|t| \le 2\sqrt{q}$.

 Caley-Hamilton: Frobenius map φ should satisfy its own characteristic polynomial

$$\varphi^2 - t\varphi + q = 0.$$

- There exist polynomials Ψ_ℓ ∈ F_q[x] that vanish precisely at the ℓ-torsion points of *E* (example: Ψ₂ = x).
- For small ℓ , check for which $t' = t \mod \ell$ the relation

$$(x^{q^2}, y^{q^2}) - t'(x^q, y^q) + (q \bmod \ell)(x, y)$$

holds in $\mathbb{F}_q[x, y]/(\Psi_\ell, y^2 - x^3 - Ax - B)$. If $\prod \ell > 4\sqrt{q}$, use CRT to recover *t*.

- Using smart speed-ups by Atkin and Elkies, Schoof's algorithm has become very efficient for elliptic curves $(q \approx 10^{60} \text{ in a couple of seconds}).$
- Seems hopeless to generalize this to high genera, because of the need of explicit formulas for #Jac_{Fg}(C).
- Small advances in genus 2 by Gaudry and Schost $(q \approx 10^{24} \text{ in about a week}).$

同 ト イ ヨ ト イ ヨ ト

First step: lift the curve to characteristic 0.

Let $\overline{C}(x, y) \in \mathbb{F}_q[x, y]$ define a smooth curve in $\mathbb{A}^2_{\mathbb{F}_q}$, and write

$$\overline{A} = rac{\mathbb{F}_q[x,y]}{(\overline{C}(x,y))}$$

for its coordinate ring.

- Write $q = p^n$ where p is the field characteristic.
- Let \mathbb{Q}_q be the unramified degree *n* extension of \mathbb{Q}_p .
- Let \mathbb{Z}_q be its ring of integers. This is a complete DVR with local parameter p and residue field \mathbb{F}_q .
- Let $C(x, y) \in \mathbb{Z}_q[x, y]$ be such that it reduces to $\overline{C}(x, y)$ mod p and write

$$A=\frac{\mathbb{Z}_q[x,y]}{(C(x,y))}.$$

Problem: Geometric properties of C/\mathbb{Q}_q depend on the choice of the lift: different genus, different endomorphism ring, ...

Define

$$\mathbb{Z}_{q}\langle \boldsymbol{x}, \boldsymbol{y} \rangle^{\dagger} = \left\{ \sum_{i,j \in \mathbb{N}} \boldsymbol{a}_{ij} \boldsymbol{x}^{i} \boldsymbol{y}^{j} \middle| \exists \rho \in]0, 1[: \frac{|\boldsymbol{a}_{ij}|_{\boldsymbol{p}}}{\rho^{i+j}} \to 0 \text{ if } i+j \to \infty \right\}.$$

• Note that $\mathbb{Z}_q\langle x, y \rangle^{\dagger}$ is closed under integration and that there is a natural map $\pi : \mathbb{Z}_q\langle x, y \rangle^{\dagger} \to \mathbb{F}_q[x, y]$.

Define

$${\mathcal A}^{\dagger} = rac{\mathbb{Z}_{{\boldsymbol q}}\langle {\boldsymbol x}, {\boldsymbol y}
angle^{\dagger}}{({\boldsymbol C}({\boldsymbol x}, {\boldsymbol y}))}.$$

Theorem (Monsky, Washnitzer):

 A^{\dagger} does not depend on the choice of *C*, and for every morphism $\overline{\varphi}: \overline{A} \to \overline{A}$ there exists a morphism $\varphi: A^{\dagger} \to A^{\dagger}$ that lifts $\overline{\varphi}$ in the sense that $\overline{\varphi} \circ \pi = \pi \circ \varphi$.

Consider the module of differentials

$$D^{1}(A^{\dagger}) = \frac{A^{\dagger} dx + A^{\dagger} dy}{\left(\frac{\partial C}{\partial x} dx + \frac{\partial C}{\partial y} dy\right)}$$

and let $d: A^{\dagger} \to D^1(A^{\dagger})$ be the usual exterior derivation. Then define the cohomology space

$$H^1_{MW}(\overline{A}/\mathbb{Q}_q) = rac{D^1(A^\dagger)}{d(A^\dagger)} \otimes_{\mathbb{Z}_q} \mathbb{Q}_q.$$

Every \mathbb{Z}_q -algebra morphism $\varphi: A^{\dagger} \to A^{\dagger}$ induces a map

$$arphi^*: \mathsf{D}^1(\mathsf{A}^\dagger) o \mathsf{D}^1(\mathsf{A}^\dagger): \mathit{fdx} + \mathit{gdy} \mapsto arphi(\mathit{f}) \mathit{d}arphi(x) + arphi(\mathit{g}) \mathit{d}arphi(y)$$

which is well-defined on $H^1_{MW}(\overline{A}/\mathbb{Q}_q)$.

Theorem (Monsky, Washnitzer):

Let $\overline{\mathcal{F}}_q: \overline{A} \to \overline{A}: a \mapsto a^q$ and let $\mathcal{F}_q: \overline{A}^{\dagger} \to \overline{A}^{\dagger}$ be a lift. Then

$$Z_{\overline{C}}(T) = rac{\det \left(\mathbb{I} - q \mathcal{F}_q^{*-1} T \ \Big| \ H^1_{MW}(\overline{A}/\mathbb{Q}_q)
ight)}{(1 - qT)}$$

If $\chi(T)$ is the characteristic polynomial of \mathcal{F}_q^* acting on $H^1_{MW}(\overline{A}/\mathbb{Q}_q)$, then one can verify that

$$Z_{\overline{C}}(T) = rac{1}{q^{g+R-1}}\chi(qT) \ (1-qT)$$

where R is the number of points at infinity.

◆□→ ◆ □ → ◆ □ → □ □

Kedlaya's method:

- Compute a lift of Frobenius \mathcal{F}_q .
- Compute a basis of $H^1_{MW}(\overline{A}/\mathbb{Q}_q)$.
- Let \mathcal{F}_{q}^{*} act on this basis.
- Re-express the result in terms of the basis, hence obtain a matrix of Frobenius.
- Compute its characteristic polynomial.
- By Weil's theorem, it suffices to do this modulo a certain *p*-adic precision.
- Problem: the resulting algorithms have running time O(q) and are therefore slower than generic methods.
- Solution if *n* is big and *p* is small: split up $\overline{\mathcal{F}_q} = \overline{\mathcal{F}_p} \circ \cdots \circ \overline{\mathcal{F}_p}$ \rightsquigarrow running time becomes typically O(p).
- Hopeless if p is big.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

So far:

- Elliptic curves, in slightly different framework (Satoh, ...): works extremely fast ($q \approx 10^{60}$ in a fraction of a second).
- Hyperelliptic curves (Kedlaya, Denef, Vercauteren): works fast (matter of seconds for cryptographic ranges and high genera).
- Superelliptic curves (Gaudry, Gürel): idem.
- C_{ab} curves (Denef, Vercauteren): slow performance due to different Frobenius lifting technique.
- Nondegenerate curves (curves in toric surfaces) (C., Denef, Vercauteren): idem.

<回>< E> < E> < E> = E

Deformation (Lauder):

Idea: put the curve of interest into a 1-parameter family

with $\overline{S} = \mathbb{F}_q[t, \overline{r}(t)^{-1}].$

- Define the relative cohomology as above, now taking coefficients in a ring S[†].
- 'Specifying' $t = t_0$ gives us the cohomology of the fibre above t_0 .

The relative matrix of Frobenius F(t) can be computed from an initial value by solving a differential equation

$$N \cdot F - rac{d}{dt}F = qt^{q-1} \cdot F \cdot N(t^q),$$

where *N* is easy to compute (Gauss-Manin connection).

Lauder's idea: take as initial value an 'easy' curve (e.g. one whose actual field of definition is a small subfield of F_q), compute F(t) and specify at the curve of interest.

(日本) イヨト イヨト

Advantages:

- Avoid slow lifting of Frobenius.
- Algorithms become more memory efficient.
- Finding curves with prime order Jacobian is easier: specify at various values in the family.

So far:

- Works already well in elliptic and hyperelliptic case (Hubrechts).
- Gives satisfactory results in *C*_{ab} case (C., Hubrechts, Vercauteren).
- Probably as well in nondegenerate case (Tuitman, in progress)

Deformation might be the key towards dealing with arbitrary curves!

Remember: all this is over fields of small characteristic.

◆□● ◆ 三 → ◆ 三 → 三 三

Some overall remarks on *p*-adic methods.

The theoretical framework is very robust, results in algorithms that have polynomial running time in the genus, and applies to a wide range of varieties. In fact:

Theorem (Lauder, Wan):

If we fix the field characteristic p and the dimension n, there exists a polynomial running time algorithm (although nonpractical) to compute the zeta function of an arbitrary polynomial in n variables.

- Dependency on p is O(p), but in case of hyperelliptic curves this has been reduced to O(√p) by Harvey → outperforms generic methods from genus 3 on.
- Interesting question: can deformation be done in $O(\sqrt{p})$?

That's it (phew)!

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □
